CRPAQS Data Analysis Workshop - March 9 & 10, 2004

T&B Systems

Task 1.3

Adequacy and validity of the surface and upper-air meteorological measurement variables

1. Review and summary of methods
2. Mechanical vs. sonic wind measurements
3. Spatial representativeness of low wind measurements
4. Validity of two-component sodar
5. Adequacy of the RASS vertical coverage
6. RASS range gate impact on observations
7. Usefulness of aircraft temperature soundings
8. Temporal adequacy of surface measurements

1. *Review and summary of methods*

Method

- ⇒ Begin with STI's existing inventory
- ⇒ Summarize additional sources of data

Results

- ⇒ Work in progress
- ⇒ Summary dependent on results from other subtasks

2. *Mechanical vs. sonic wind measurements*

Method

- ⇒ Obtained subset of sonic data
- ⇒ Processed into 5-minute intervals

Results

- ⇒ Little difference between data sets for wind speed and wind direction
- ⇒ No significant biases, even under low wind speeds

2. Mechanical vs. sonic wind measurements

2. Mechanical vs. sonic wind measurements

Sonic vs Mechanical WS Comparison - 25 m
Relative Difference (Mechanical - Sonic)

Sonic vs Mechanical WS Comparison - 25 m
WS < 1 m/s
Relative Difference (Mechanical - Sonic)

3. Spatial representativeness of low wind measurements

Method

⇒ Missing 20-meter tower data

Results

⇒ Analysis not performed

4. *Validity of two-component sodar*

Method

- ⇒ Sodar winds compared with 100-meter tower data
- ⇒ Only 98-m level available for comparison

Results

- ⇒ Significant differences, especially for wind speed
- ⇒ Sodar data for trajectory analysis may be limited

4. *Validity of two-component sodar*

Sodar / Tower Comparison
Wind Direction - 100 m
December 2000

Sodar / Tower Comparison
Wind Speed - 100 m
December 2000

4. *Validity of two-component sodar*

| Mechanical WS (m/s) | Correlation (r) | | Average WS (m/s) | | N |
|------------------------|-----------------|-------|------------------|-------|-----|
| | WS | WD | Mechanical | Sodar | |
| 0 – 0.5 | 0.263 | 0.775 | 0.30 | 0.57 | 24 |
| 0.5 – 1 | 0.018 | 0.886 | 0.77 | 0.86 | 56 |
| 0 – 1 | 0.303 | 0.828 | 0.61 | 0.77 | 80 |
| > 1 | 0.823 | 0.960 | 2.71 | 2.24 | 215 |

4. *Validity of two-component sodar*

5. Adequacy of the RASS vertical coverage

Method

- ⇒ RASS and 100-m tower data merged for three IOPs
- ⇒ Soundings categorized into 10 types based on ability to identify top of mixing layer

Results

- ⇒ Approximately 1/3 of soundings problematic for identifying top of mixing layer
- ⇒ Inaccuracies in RASS may compound problems

5. Adequacy of the RASS vertical coverage

5. Adequacy of the RASS vertical coverage

6. RASS range gate impact on observations

Method

- ⇒ Compared RASS data with 39 rawinsonde soundings from audits at 11 sites
- ⇒ Calculated and compared inversion strength (lapse rate) for both methods

Results

- ⇒ Approximately 1/4 of the inversions were not identified by RASS
- ⇒ RASS underestimated inversion strength by 67%

6. RASS range gate impact on observations

6. RASS range gate impact on observations

| Sites | Inversions (N) | Average Inversion Strength Audit (°C/100 m) | Average Inversion Strength RASS (°C/100 m) | Average Percent Difference |
|----------------------|-------------------|---|--|----------------------------------|
| All | 35 | 1.37 | 0.41 | -67% |
| Sites with 60 m gate | 15 | 1.44 | 0.51 | -54% |
| Sites with 105m gate | 20 | 1.31 | 0.33 | -76% |
| | | | | |

8. Temporal adequacy of surface measurements

Method

- ⇒ Used 5-min and 1-hr average wind data
- ⇒ Calculated and compared 1-hr wind run using both sets for December 2000

Results

- ⇒ Differences between two data sets do not appear significant

8. Temporal adequacy of surface measurements

| Scalar WS range (m/s) | N | Average Scalar WS (m/s) | Average Vector WS (m/s) | Average hourly wind run – 5 min averages (km) | Average hourly wind run – 1 hr averages (km) | Diff. (km) |
|-----------------------------|-----|-------------------------------|-------------------------------|---|--|---------------|
| 0 – 1 | 121 | 0.75 | 0.58 | 2.59 | 2.09 | 0.50 |
| 1 – 1.5 | 141 | 1.25 | 1.07 | 4.40 | 3.87 | 0.53 |
| 1.5 – 2 | 160 | 1.75 | 1.61 | 6.21 | 5.79 | 0.42 |
| 2 – 2.5 | 95 | 2.22 | 2.01 | 7.91 | 7.43 | 0.48 |
| 2.5 – 3 | 60 | 2.74 | 2.65 | 9.80 | 9.54 | 0.26 |
| > 3 | 76 | 3.74 | 3.65 | 13.37 | 13.14 | 0.23 |
| All | 653 | 1.85 | 1.70 | 6.56 | 6.13 | 0.43 |

8. Temporal adequacy of surface measurements

7. Usefulness of aircraft temperature soundings

Method

- ⇒ Compared aircraft soundings with rawinsonde data at Fresno and Bakersfield
- ⇒ Used Holzworth method for determining mixing heights

Results

- ⇒ Comparison results remarkably good at Fresno
- ⇒ Less agreement at Bakersfield, possibly due to systematic differences between contractors

7. Usefulness of aircraft temperature soundings
